

CLAIMS

1. A holographic recording method for converting digital information to a two-dimensional image, allowing an object beam to be subjected to spatial optical modulation based on 5 the two-dimensional image, and irradiating a holographic recording medium with the object beam in conjunction with a reference beam to record the two-dimensional image using interference fringes, wherein

with four or more pixels on the two-dimensional image 10 employed as a unit pixel block, encoded patterns having a different number of ON pixels are allowed to be present at the same time in the unit pixel block to record the two-dimensional image.

2. The holographic recording method according to claim 1, 15 wherein

when the number of pixels forming the unit pixel block is n, the number of the encoded patterns is a total sum of nC_0 to nC_n .

3. A holographic memory reproduction method for 20 reproducing digital information, the digital information being recorded by converting the digital information to a two-dimensional image, and irradiating a holographic recording medium with an object beam having been subjected to spatial optical modulation based on the two-dimensional image, in 25 conjunction with a reference beam to record the two-

dimensional image using interference fringes, wherein
the two-dimensional image is recorded, with four or more
pixels employed as a unit pixel block and at least two types
of encoded patterns having a different number of ON pixels in
5 the unit pixel block being allowed to be present at the same
time, and

10 during a reproduction operation, the number of ON pixels
is detected on the per unit pixel block basis, and a threshold
of a detected beam intensity between ON and OFF in a two-
dimensional image detector used for image detection is set
based on the number of ON pixels detected.

4. The holographic memory reproduction method according
to claim 3, wherein

15 when the number of pixels in the unit pixel block is n,
the number of types of the encoded patterns provided is equal
to a total sum N of nC_0 to nC_n , and n types of settings are
provided for the threshold of the detected beam intensity.

20 5. A holographic recording apparatus for converting
digital information to a two-dimensional image, allowing an
object beam to be intensity modulated using a spatial light
modulator based on the two-dimensional image, and irradiating
a holographic recording medium with the object beam in
conjunction with a reference beam to record the two-
dimensional image using interference fringes, wherein
25 the spatial light modulator is configured to display a

two-dimensional image, with four or more pixels on the two-dimensional image employed as a unit pixel block and with at least two types of encoded patterns having a different number of ON pixels in the unit pixel block being allowed to be 5 present at the same time.

6. The holographic recording apparatus according to claim 5, wherein

when the number of pixels in the unit pixel block is n , the spatial light modulator is configured to display encoded 10 patterns of types equal in number to a total sum N of nC_0 to nC_n .

7. A holographic memory reproduction apparatus for reproducing digital information by a two-dimensional photodetector used for image detection, the digital information being recorded by converting the digital 15 information to a two-dimensional image, and irradiating a holographic recording medium with an object beam having been subjected to spatial optical modulation based on the two-dimensional image, in conjunction with a reference beam to record the two-dimensional image using interference fringes, 20 wherein

the two-dimensional image is recorded, with four or more pixels employed as a unit pixel block and with at least two types of encoded patterns having a different number of ON pixels in the unit pixel block being allowed to be present at 25 the same time, and

the holographic memory reproduction apparatus has an ON pixel number detector for detecting the number of ON pixels on the per unit pixel block basis, and a threshold setter for setting a threshold of a detected beam intensity between ON and OFF in the two-dimensional photodetector based on the 5 number of ON pixels detected by the ON pixel number detector.

8. The holographic memory reproduction apparatus according to claim 7, wherein

when the number of pixels in the unit pixel block is n, 10 the number of types of encoded patterns displayed by the spatial light modulator is set to be equal to a total sum N of nC_0 to nC_n , and the threshold setter is allowed to provide n types of settings for the threshold.
